Serotonin is synthesized in carcinoid cells from tryptophan, which is also used in the production of niacin or nicotinic acid. Advanced disease results in increased tryptophan conversion to serotonin and its metabolite 5-hydroxyindoleacetic acid. This may result in tryptophan and niacin deficiency causing pellagra (with diarrhea, dermatitis, glossitis, angular stomatitis, and dementia).

primary adrenal disease.

The initial step in the evaluation is to confirm **hypercortisolism** with a late-night salivary cortisol assay, 24-hour urine free cortisol measurement, and/or overnight low-dose dexamethasone suppression test. Two of these first-line tests should be abnormal to establish the diagnosis. If hypercortisolism is confirmed, ACTH levels are measured to differentiate ACTH-dependent (ie, Cushing disease, ectopic ACTH) from ACTH-independent (eg, adrenal adenoma) causes (**Choice C**).

This patient has several features suggesting **Cushing syndrome** (hypercortisolism). Weight gain, proximal muscle weakness, and hypertension are common presenting findings. Patients can experience easy **bruisability**, dermal atrophy, and wide purple striae due to the catabolic effects of cortisol on connective tissue; however, platelet function and coagulation proteins are normal. Dermatologic signs may include **hyperpigmentation** (in ACTH-dependent Cushing syndrome) and **increased incidence of cutaneous fungal infections** (eg, tinea versicolor, onychomycosis). Women can have features of **hyperandrogenism** (eg, menstrual irregularities, acne, hirsutism) due to co-secretion of adrenal androgens with cortisol.

DI can be central (decreased antidiuretic hormone [ADH] secretion from the pituitary) or nephrogenic (normal ADH levels with renal ADH resistance). Central DI patients usually do not have an intact thirst mechanism and can have serum sodium >150 mEq/L. Nephrogenic DI patients usually have an intact thirst mechanism with lower serum sodium (~145 mEq/L). However, some cases may not be clinically obvious. A water deprivation test can distinguish between central and nephrogenic DI and also definitively exclude primary polydipsia.

Diabetes mellitus increases the risk for cardiovascular events, renal disease, and blindness. The prevalence of diabetes in the United States is increasing. However, current guidelines differ regarding screening for diabetes in asymptomatic patients:

- The **US Preventive Services Task Force (USPSTF)** recommends screening in patients with sustained blood pressure (treated or untreated)  $>135/80$  mm Hg. However, there is insufficient evidence to establish the benefits of screening patients with blood pressure  $\leq 135/80$  mm Hg.
- The **American Diabetes Association** recommends screening in all patients age  $\geq 45$  years, as well as those at any age with additional **risk factors for diabetes**.

**(Choice E)** The 13-valent pneumococcal conjugate vaccine (PCV13) is recommended for all adults age  $\geq 65$ , followed by the 23-valent pneumococcal polysaccharide vaccine (PPSV23) 6-12 months later. Sequential PCV13 and PPSV23 are also recommended for adults age  $<65$  with certain very high-risk underlying conditions (eg, cerebrospinal fluid leaks, sickle cell disease, cochlear implants, congenital or acquired asplenia, immunocompromised status, chronic renal failure). PPSV23 alone is recommended for adults age  $<65$  who are current smokers or have certain chronic medical conditions, including heart or lung disease, diabetes, and chronic liver disease.

## Diabetes risk factors in adults with BMI >25 kg/m<sup>2</sup>

- Physical inactivity
- First-degree relative with diabetes
- High-risk race/ethnicity (eg, African American, Latino, Native American, Asian, Pacific Islander)
- Women whose children's birth weight ≥9 lb
- History of gestational diabetes mellitus
- Hypertension or prior cardiovascular disease
- Dyslipidemia (low HDL & high triglyceride level)
- History of polycystic ovarian syndrome
- History of glucose intolerance

## GLP-1 agonists & DPP-IV inhibitors

©UWorld

Intensive blood pressure (BP) control is the primary intervention proven to slow the decline in GFR once azotemia develops. Most patients with diabetes mellitus should be treated toward a target BP of 140/90 mm Hg, and patients with diabetic nephropathy may benefit from more intensive BP control. Most guidelines now recommend a target BP of 130/80 mm Hg for patients who are diabetic with signs of nephropathy. Angiotensin-converting enzyme (ACE) inhibitors, and perhaps angiotensin receptor blockers (ARBs), are the preferred antihypertensive drugs for patients with diabetes mellitus. These drugs may have actions in addition to BP control, such as reducing intraglomerular pressure, which may be renoprotective. However, ACE inhibitors or ARBs in patients with diabetic nephropathy must be initiated carefully as they may induce an acute decline in GFR and hyperkalemia.

**(Choice D)** Intensive glycemic management ( $Hb_{A1c} < 7.0\%$ ) has been shown to reduce the occurrence and progression of microalbuminuria. However, a more aggressive reduction of glycemic control beyond this target is associated with an increased risk for hypoglycemia and may actually increase the risk for cardiac events.

**(Choice E)** Animal studies have found that dietary restriction of protein results in a decrease in protein excretion, as well preservation of GFR; however, studies in humans are conflicting. Generally, a diet consisting of 0.8 g/kg/day of protein is recommended for patients with diabetic nephropathy and azotemia.

Symmetric distal **sensorimotor polyneuropathy** is the most common neuropathy in patients with diabetes, and clinical features depend on the type of nerve fibers involved.

- **Small fiber** injury is characterized by predominance of **positive symptoms** (eg, pain, paresthesias, allodynia) (**Choice B**).
- **Large fiber** involvement is characterized by predominance of **negative symptoms** (eg, numbness, loss of proprioception and vibration sense, diminished ankle reflexes).

DKA = diabetic ketoacidosis; HHS = hyperglycemic hyperosmolar nonketotic state

The best markers indicating resolution of **ketonemia** are the **serum anion gap** and direct assay of **beta-hydroxybutyrate (BH)**, which is the predominant ketone in DKA. The anion gap estimates the unmeasured anion concentration in the blood and returns to normal with the elimination of ketoacid anions. BH is converted to acetoacetate and acetone, which can be measured by the commonly used nitroprusside test, but this test does not detect BH itself. Therefore, either calculation of the anion gap or direct assay of serum BH is recommended to follow ketonemia (**Choice A**). A rise in serum bicarbonate and arterial pH provides further confirmation of the improvement in acidosis.

This patient's symptoms are suggestive of diabetic autonomic neuropathy of the gastrointestinal tract, with predominant symptoms of delayed gastric emptying, or gastroparesis. Diabetic autonomic neuropathy occurs in >50% of patients with longstanding type 1 or 2 diabetes mellitus and can manifest as disorders of esophageal motility (eg, dysphagia), gastric emptying (eg, gastroparesis), or intestinal function (eg, diarrhea, constipation, incontinence). Gastroparesis presents with symptoms of anorexia, nausea, vomiting, early satiety, or postprandial fullness. Hypoglycemic episodes can occur with insulin administration prior to meals in patients with impaired gastric emptying or delayed absorption.

Treatment of patients with diabetic gastroparesis includes a combination of optimizing diabetes control; dietary modifications with increased fiber intake and **small, frequent meals**; and medications to improve gastric emptying. **Metoclopramide** has both prokinetic and antiemetic properties and is useful for symptomatic relief of nausea, bloating, and postprandial fullness in patients with diabetic gastroparesis. The use of metoclopramide can be associated with a small (<1%) risk of extrapyramidal side effects (eg, tardive dyskinesia). Other alternate therapeutic options include **erythromycin** (more useful when used intravenously for acute exacerbations) and cisapride (restricted use in the United States due to the risk of cardiac arrhythmias and death).

**(Choice D)** Progesterone analogs (eg, megestrol acetate, medroxyprogesterone acetate) are useful in the palliation of anorexia and in improving appetite and weight gain in patients with cancer-related anorexia/cachexia syndrome. They have no role in the treatment of patients with diabetic gastroparesis.

The liver maintains glucose levels in the blood via **glycogenolysis** and **gluconeogenesis**. During fasting states, glycogen reserves drop dramatically in the first 12 hours, by which time gluconeogenesis starts to play an important role. After 24 hours, gluconeogenesis represents the sole source of glucose production. The main substrates for gluconeogenesis are **gluconeogenic amino acids** (from breakdown of muscle protein), **lactate** (from anaerobic glycolysis), and **glycerol 3-phosphate** (from triacylglycerol in adipose). Alanine is the major gluconeogenic amino acid in the liver, and it is converted into pyruvate by alanine aminotransferase. Pyruvate is eventually converted to glucose through a series of reactions, and free glucose is then released into the bloodstream.

## Causes of hypertension & hypokalemia

**(Choices A and D)** Aldosterone increases sodium reabsorption (saves sodium), potassium secretion, and hydrogen secretion in the distal renal tubules. The sodium reabsorption also leads to water absorption. However, this is countered in a few days by a spontaneous diuresis that lowers the water and sodium (aldosterone escape). This returns the volume status to slightly above normal and results in mild hypernatremia (143-147 mEq/L) without significant peripheral edema. The hypokalemia directly increases renal bicarbonate resorption, which, combined with increased hydrogen secretion, results in metabolic alkalosis.

| Multiple endocrine neoplasia type 1          |                                                                                                                                                                                                                                                                                      |

which promote the movement of potassium out of cells into the extracellular space. Despite normal serum levels, patients with HHS or DKA have a total body potassium deficit (3–5 mg/kg) due to excessive urinary loss caused by osmotic diuresis induced by hyperglycemia. The clinical implication of potassium depletion is that insulin therapy for HHS can abruptly lower serum potassium levels and cause severe hypokalemia.

©UWorld

- Maternal anti-TSH measured at 22 wks of gestation
- Current recommendations state that once the patient complains of fever and sore throat, the antithyroid drug should be discontinued promptly and the WBC count measured. A total WBC count less than 1,000/cubic mm warrants permanent discontinuation of the drug. If the total WBC count is more than 1,500 per cubic mm, antithyroid drug toxicity is unlikely to be the cause of the sore throat and fever.

- Hypomagnesemia is very common in hospitalized alcoholics and can cause hypocalcemia by inducing resistance to parathyroid hormone (PTH) as well as by decreasing PTH secretion. The cause of hypomagnesemia in alcoholics is multifactorial, and may include urinary losses, malnutrition, acute pancreatitis, and diarrhea.

| Acute hypocalcemia       |                                                                                                                                                                                                                                                                            |

EDTA = ethylenediaminetetraacetic acid.

- Hypocalcemia is uncommon following blood transfusion in patients with normal liver function as citrate is rapidly metabolized by the liver; however, this patient likely has hepatic dysfunction due to the liver laceration as well as ischemic liver injury due to hypotension. Other infused substances that can chelate calcium in the blood include lactate, foscarnet, and sodium ethylenediaminetetraacetic acid (EDTA).

**(Choice D)** Hypomagnesemia (not hypermagnesemia) can present similarly to hypocalcemia. Severe hypermagnesemia causes hyporeflexia, paralysis, apnea, and cardiac arrest. Rarely, very severe hypermagnesemia can cause hypocalcemia by inhibiting parathyroid hormone release, but this would typically be seen with infusions of magnesium, such as in the treatment of severe preeclampsia and eclampsia.

The causes of primary hypoparathyroidism include:

1. Post-surgical (most common cause)
2. Autoimmune
3. Congenital absence or maldevelopment of the parathyroid glands (eg, DiGeorge syndrome)
4. Defective calcium-sensing receptor on the parathyroid glands
5. Non-autoimmune destruction of the parathyroid gland due to infiltrative diseases such as hemochromatosis, Wilson disease, and neck irradiation

In normal individuals, a blood glucose level below 60 mg/dL results in near-complete suppression of insulin secretion. The patient in this vignette thus presents with hypoglycemia and inappropriately elevated serum insulin levels.

There are two important causes of hypoglycemia in non-diabetic patients with elevated insulin levels:

1. insulinoma (beta cell tumor)
2. surreptitious use of insulin or sulfonylurea

Elevated C-peptide levels and proinsulin levels greater than 5 pmol/L are seen in patients with beta cell tumors; therefore, this is the most likely diagnosis.

**(Choice B)** Non-beta cell tumors, typically large mesenchymal tumors, can lead to hypoglycemia independent of insulin. Such tumors produce insulin-like growth factor II (IGF II), which has an insulinomimetic action after binding to insulin receptors. In patients with suspected non-beta cell tumors, the serum IGF II level can be measured. Patients with this condition characteristically have suppressed insulin and c-peptide levels.

**(Choice C)** Sulfonylurea causes an increased output of endogenous insulin from the beta cells. Patients with sulfonylurea-induced hypoglycemia are sometimes difficult to differentiate from those with insulinoma because increased insulin and c-peptide levels are seen in both groups. Nonetheless, the proinsulin level is sometimes lower than 20% of the total insulin immunoreactivity. The diagnosis is confirmed by measuring the plasma sulfonylurea level.

**(Choice D)** Exogenous insulin-induced hypoglycemia is associated with very high serum insulin levels combined with low c-peptide levels. The low c-peptide levels result from the suppression of endogenous insulin production.

|                   | Primary<br>(testicular disease)                                                                                                                                                                                                                                                                                                                                                                 | Secondary<br>(pituitary/hypothalamic disease)                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Hypothyroidism can cause additional metabolic abnormalities such as hyperlipidemia, hyponatremia and asymptomatic elevations of creatinine kinase (usually <10x normal) and serum transaminases (aspartate aminotransferase and alanine aminotransferase). Hypercholesterolemia with high low-density lipoprotein (LDL) is due primarily to decreased surface LDL receptors (type 2a hyperlipidemia) and/or decreased LDL receptor activity. Hypothyroidism can also decrease lipoprotein lipase activity to cause hypertriglyceridemia.

Most hypothyroid patients have either hypercholesterolemia alone or combined hypertriglyceridemia and hypercholesterolemia. Isolated hypertriglyceridemia due to hypothyroidism is rare. The lipid abnormalities may take months to resolve despite adequate treatment of hypothyroidism. Statins can increase the risk of myopathy in poorly controlled hypothyroidism and should be given with caution in these patients.

**(Choice B)** Hypothyroidism can cause hyponatremia due to decreased free water clearance. Hypothyroidism and adrenal insufficiency must be ruled out before diagnosing the syndrome of inappropriate antidiuretic hormone. However, hypothyroidism does not usually cause hypernatremia.

**(Choice C)** Serum calcium is usually normal in hypothyroidism unless a patient has coexisting hypoparathyroidism (eg, polyglandular autoimmune failure or surgical complication during thyroid surgery). However, thyrotoxicosis can cause hypercalcemia and is due to increased bone resorption.

**(Choices D and E)** Hypothyroid patients most commonly develop normocytic, normochromic anemia due to decreased red blood cell mass. Chronic autoimmune thyroiditis may cause pernicious anemia, but some patients can have macrocytosis without megaloblastic anemia. Some hypothyroid patients may develop acquired von Willebrand syndrome with increased bleeding risk; resultant menorrhagia can sometimes cause iron deficiency anemia in women of reproductive age. However, hypothyroidism is less commonly associated with thrombocytopenia and neutropenia.

**myopathy.** Myopathy occurs in over one third of patients with hypothyroidism, and can range from an asymptomatic elevation in CK to myalgias, muscle hypertrophy, proximal myopathy, and rhabdomyolysis. Serum CK can be elevated for years before a patient develops clinical symptoms of hypothyroidism, and there is no clear correlation between the degree of CK elevation and severity of muscle disease. Inflammatory markers (eg, erythrocyte sedimentation rate, C-reactive protein) may be normal or mildly elevated.

| Euthyroid sick syndrome |            |                  |
|-------------------------|------------|------------------|
|                         | Early/mild | Prolonged/severe |
| <b>T3</b>               | ↓          | ↓                |
| <b>T4</b>               | Normal     | ↓                |
| <b>TSH</b>              | Normal     | ↓                |
| <b>Reverse T3</b>       | ↑          | ↑                |

This patient with low serum (total) T3, normal serum (total) T4, and normal TSH in the setting of acute illness (eg, ulcerative colitis flare treated with glucocorticoids) has **euthyroid sick syndrome (ESS)**.

T4 is produced exclusively in the thyroid gland, whereas T3 is produced mainly by peripheral conversion of T4 by deiodination. ESS encompasses a variety of alterations in thyroid physiology, the most common of which is termed "**low T3 syndrome**" and is thought to be the result of **decreased conversion** of T4 to T3. Factors in acute illness that inhibit peripheral deiodination include high endogenous cortisol levels, inflammatory cytokines (eg, tumor necrosis factor), starvation, and certain medications (eg, **glucocorticoids**, amiodarone).

**(Choices A and C)** Hospitalized patients, particularly those in intensive care units, can have reduced levels of plasma binding proteins (eg, thyroxine-binding protein, transthyretin, albumin). Because most T4 circulates in bound form, this leads to a significant drop in total T4 levels, although free hormone levels are unaffected. The serum (total) T4 level is normal in this patient.

**(Choice D)** Thyroid hormones undergo significant enterohepatic circulation, with reabsorption in the jejunum and upper ileum. Excessive fecal loss of thyroid hormone can occur in small intestinal disease (eg, Crohn disease, celiac disease). Ulcerative colitis does not directly involve the small intestine and is unlikely to affect reabsorption.

### Management of hyperprolactinemia in premenopausal women

| Prolactinoma overview      |                                                                                                                                                                                                                                                                                                                                              |
